Background and Aims: The present study was designed to evaluate photo-degradation of Dacarbazine (DTIC), a photo unstable anti-cancer drug , in aqueous solution by using UV-spectroscopic and chemometrics methods. Unfortunately, previous studies were done by HPLC method that was expensive and time-consuming. Moreover, the samples need to be frozen for analysis procedure and it could be degraded during this process.

Methods: The commercial formulation of DTIC was reconstituted with deionized water to concentration of 0.04 mg/ml then it was exposed to indoor light that is combination of fluorescent and UV light for 4 hours. In order to protect the sample s from photo-degradation, all the procedures were done under sodium light. The samples were placed in a light box 20 cm away from light source and immediately were analyzed by UV-spectrophotometer.

Results: The fresh reconstituted solution has max 322 nm. After being exposed to light the absorption decreased and new stable photo-product was formed with max 236 and 275 nm. What’s more, this new compound was colourless.

Conclusions: This new method is time-saving and accurate enough to distinguish the process of photo-degradation. In this study we found at least two Photo-degraded products. Moreover, It will be possible to study the kinetic of this photo-degradation reaction. At this time we are doing several experiments to validate this method.
